BACKGROUND OF THE INVENTION

5 1. Field of the Invention:

The present invention relates to a novel protease which specifically cleaves the peptide bond at the carboxyl termini of glutamic acid residues in the amino acid sequences of polypeptides, a method for producing the protease from bacteria of the genus Bacillus, a DNA sequence encoding the protease, an expression vector containing the DNA sequence, a transformant obtained by introducing this expression vector into a host, and a method for producing the protease using the transformant.

2. Description of the Prior Art:

15 The V8 protease derived from the V8 strain of Staphylococcus aureus is already known as an enzyme which acts upon proteins (i.e., polypeptides) and specifically cleaves the peptide bond at the carboxyl terminal of glutamic acid (Glu) residues (Gabriel R. Drapeau et al., J. Biol. Chem. 247, 20, 6720-6726, 1972). This enzyme is classified as a serine protease. C. Carmona et al. have cloned the DNA sequence encoding this enzyme (Nucl. Acids Res., 15, 6757, 1987).

20 A similar enzyme, an endopetidase which is specific for acidic amino acid residue and is derived from an actinomycete bacterium Streptomyces griseus, is also known (Norio Yoshida et al., J. Biochem. 104, 3, 451-456, 1988). Furthermore, an endoprotease which is specific for glutamic acid residue derived from Bacillus subtilis is also known (Takuro Niidome, Norio Yoshida, Fusahiro Ogata, Akio Ito, and Kosaku Noda, J. Biochem. 108, 965-970, 1990; Abstracts of 62nd General Conference of the Japan Biochemical Society).

25 The aforesaid enzymes are useful when specific cleavage of proteins at the aforesaid sites is desired for the purposes of protein structural analysis, etc., or when recombinant DNA techniques have been employed to produce a desired protein in the form of a certain fusion protein, from which the desired protein is to be obtained by cleavage. In the latter case, for example, when the desired protein has been produced in the form of a fusion protein in which the desired protein is linked with another protein via a glutamic acid residue, the desired protein can be separated by cleavage with such an enzyme. For these reasons, the availability of other proteases possessing this type of enzymatic activity, in addition to those mentioned above, would be highly desirable.

SUMMARY OF THE INVENTION

35 The novel protease of this invention, which overcomes the above-discussed and numerous other disadvantages and deficiencies of the prior art, is derived from Bacillus licheniformis. The protease cleaves the peptide bonds at the carboxyl termini of glutamic acid residues in polypeptides, and contains an amino acid sequence from serine in the +1 position to glutamine in the +222 position of SEQ ID NO: 1.

40 In a preferred embodiment, the protease is derived from Bacillus licheniformis ATCC No. 14580.

In a preferred embodiment, the protease has the following properties:

- (1) Optimal pH: approximately 8.0, and
- (2) Stable pH range: pH 6.5-8.5 at 25 °C.

45 In a preferred embodiment, the protease contains an amino acid sequence from serine in the +1 position to glutamine in the +222 position of SEQ ID NO: 1, and cleaves the peptide bonds at the carboxyl termini of glutamic acid residues in polypeptides.

The DNA sequence of this invention encodes the above-mentioned protease.

In a preferred embodiment, the DNA sequence contains a base sequence from the thymine residue in the 605 position to the adenosine residue in the 1270 position of SEQ ID NO: 1.

50 In a preferred embodiment, the DNA sequence encodes a protease containing an amino acid sequence from N-formylmethionine at the -94 position to the glutamine at the +222 position of SEQ ID NO: 1.

In a preferred embodiment, the DNA sequence contains a base sequence, from the thymine residue in the 323 position to the adenosine residue in the 1270 position, of SEQ ID NO: 1.

The expression vector of this invention contains the above-mentioned DNA sequence.

55 In a preferred embodiment, the expression vector is expressible in bacteria of the genus Bacillus.

The transformant of this invention is obtainable by introducing the above-mentioned expression vector into a host.

In a preferred embodiment, the host is a strain belonging to the genus Bacillus.

The method for producing a protease of this invention comprises the steps of cultivating a strain of Bacillus licheniformis capable of producing the above-mentioned protease in a culture medium and recovering the produced protease from the culture medium.

The method for producing a protease of this invention comprises the steps of cultivating the above-mentioned transformant in a culture medium and recovering the produced protease from the culture medium.

It is understood that various other modifications will be apparent to and can be readily made by those skilled in the art without departing from the scope and spirit of this invention. Accordingly, it is not intended that the scope of the claims appended hereto be limited to the description as set forth herein, but rather that the claims be construed as encompassing all the features of patentable novelty that reside in the present invention, including all features that would be treated as equivalents thereof by those skilled in the art to which this invention pertains.

Thus, the invention described herein makes possible the objectives of:

- (1) providing a novel protease with an enzymatic activity of specifically cleaving polypeptides at the carboxyl termini of glutamic acid residues; and
- (2) providing a DNA sequence encoding the protease, an expression vector containing the DNA sequence, a transformant obtained by introduction of the expression vector into a host, and a method for the production of the protease using the transformant.

BRIEF DESCRIPTION OF THE DRAWINGS

This invention may be better understood and its numerous objects and advantages will become apparent to those skilled in the art by reference to the accompanying drawings as follows:

Figures 1-1 to 1-3 show the DNA sequence of the protease of the present invention and the amino acid sequence deduced from the DNA sequence.

Figure 2 is a schematic diagram illustrating the construction of the expression vector pHY300BLtt of the present invention.

Figure 3 is a schematic diagram illustrating the construction of the shuttle vector pHY300PLKtt used in the construction of the expression vector pHY300BLtt of the present invention.

Figure 4 shows graphs indicating the elution of the enzyme of the present invention from an affinity column in the process of extraction and purification of the enzyme from the medium in which Bacillus licheniformis ATCC No. 14580 was cultivated.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present inventors have conducted various studies with a view to obtaining proteases, possessing the enzymatic action of cleaving peptides at the carboxyl termini of glutamic acid residues, from microorganisms other than the aforesaid Staphylococcus aureus, etc. As a result of these researches, the present inventors have discovered a novel protease possessing the aforesaid property, derived from Bacillus licheniformis ATCC No. 14580. Furthermore, the present inventors have also found a DNA sequence encoding this protease and created an expression vector containing the DNA sequence as well as transformant obtained by introduction of the expression vector into a host, and discovered a method for the production of this protease using the transformant, thereby completing the present invention.

The protease of the present invention (hereinafter referred to as BLase) is produced by bacteria of the genus Bacillus, in particular, by Bacillus licheniformis ATCC No. 14580. This strain is available from the American Type Culture Collection (ATCC).

I. Culture conditions

No special medium is required for the cultivation of the aforesaid bacterial strain, and any of the various conventional types of culture medium are suitable for this purpose. For example, a medium containing glucose, soybean powder, meat extract, corn steep liquor, and the various inorganic salts, etc., can be used. The appropriate medium pH is 5-9, preferably approximately 7.0, the appropriate medium temperature is 15-50°C, preferably approximately 28°C, and the bacteria are cultured, for example, aerobically with stirring or shaking for approximately 36 hours. The enzyme BLase of the present invention was principally secreted extracellularly.

II. Collection of enzyme

Known processes for the collection and purification of enzymes can be used, either singly or in combination, for the collection and purification of the present enzyme from the aforesaid culture broth. For example, the culture broth can be subjected to filter pressing, ultrafiltration, and centrifugal separation, thereby obtaining a cell-free liquid concentrate. The enzyme of the present invention can then be obtained from this concentrate by an appropriate method of purification. For example, the aforesaid concentrate can be subjected first to preliminary purification by ion exchange chromatography, and then to chromatography with S-Sepharose, and finally to affinity chromatography, thereby obtaining the present enzyme. In Example 1 shown below, enzyme specimen with activity 1.9×10^3 to 2.4×10^3 U/mg (assayed by the method for the measurement of enzymatic activity described below) was obtained by this type of procedure. This enzyme specimen was used for the determination of enzyme properties described below.

III. Method for the measurement of enzymatic activity

Z-Phe Leu Glu-pNA (wherein Z is a carbobenzoxy group and pNA is a p-nitroaniline group), used as a substrate, is dissolved in 50 mM Tris-HCl (pH 7.5, containing 2 mM calcium chloride and 2% DMF) so as to achieve a final substrate concentration of 0.2 mM. An enzyme solution is added to this mixture, and a reaction is conducted at 37°C for 10 minutes, then the 410 nm absorbance of the p-nitroaniline released into the liquid by the enzymatic reaction is measured. The enzymatic activity present when this absorbance is 1.0 is defined as 1 unit (U).

IV. Enzyme properties

The enzymatic properties and protein chemical properties of BLase of the present invention are as follows.

(1) Enzymatic action and substrate specificity

(i) The synthetic substrates shown in Table 1 were prepared, and each of them was dissolved in 50 ml Tris-HCl (pH 7.5, containing 2 mM calcium chloride and dimethylformamide (DMF) or dimethyl sulfoxide (DMSO) in the proportions indicated by Table 1) so as to achieve the concentration shown in Table 1. Then, the present enzyme was added to this solution and a reaction was conducted at 25°C. The 410 nm absorbance of the p-nitroaniline released into the liquid by the enzymatic reaction was measured, and the quantity (nmol) of p-nitroaniline released from 1 mg of the substrate per minute was calculated; the results so obtained are shown in Table 1.

Table 1

Substrate	Final concentration of substrate (mM)	Concentration of DMF or DMSO (%)	Released p-nitroaniline (nmol/mg/min.)
Z Phe Leu Glu pNA*	0.05	DMF 20	246.2
Z Phe Leu Asp pNA*	0.05	DMF 20	0.0
Ac Glu pNA*	2.0	DMF 10	90.0
Ac Asp pNA*	2.0	DMF 10	0.0
Bz Tyr pNA*	0.1	DMF 10	0.0
Bz Arg pNA*	0.4	DMSO 0.8	0.0
Z Gly Ser pNA*	1.0	DMF 10	0.0
Suc Ala Ala Ala pNA*	1.0	—	0.0
Leu pNA*	10.0	DMF 10	0.0

*pNA: p-Nitroanilide

(ii) Oxidized insulin B chain was selected as a protein substrate, and the actions of the present enzyme and V8 protease derived from *Staphylococcus aureus* upon this substrate were compared by the following procedure. First, oxidized insulin B chain was dissolved in 50 mM ammonium bicarbonate (pH 7.8), the present enzyme or the aforesaid V8 protease was added so as to achieve an enzyme/substrate ratio of 1/100 (W/W), and a reaction was conducted over a prescribed period of time. The reaction

mixture was then subjected to HPLC using a 4.6 x 250 mm column packed with Vydac Protein C₄ (300 angstroms), which was eluted under a 0-50% acetonitrile linear gradient in 0.1% TFA, raising the acetonitrile concentration by 1.67%/min. Peptide mapping revealed that, when either of the enzymes was used, the peptide bonds at the carboxyl termini of the glutamic acid residues were cleaved, and the products of enzymatic hydrolysis induced by the two enzymes were identical with each other.

Thus, the results of the aforesaid analyses (i) and (ii) demonstrated that the present enzyme cleaves peptide bonds at the carboxyl termini of glutamic acid residues, and is indeed a glutamic acid specific endopeptidase.

(2) Optimal pH and stable pH range

Z-Phe Leu Glu-pNA as a substrate was dissolved in 50 mM Tris-HCl containing 10% DMF and 2 mM calcium chloride. Then, the present enzyme was added to this mixture, a reaction was conducted for 15 minutes at 37 °C, and the 410 nm absorbance of the p-nitroaniline released into the liquid by the enzymatic reaction was measured. The aforesaid reaction was conducted at various pH values, and the results revealed that the optimal pH for enzymatic activity is 8.0.

Next, the present enzyme was maintained at 25 °C for 24 hours at various pH values, and in each case the enzyme after this treatment was allowed to react with a substrate in accordance with the procedures described in the method for the measurement of enzymatic activity mentioned above. The results indicate that the stable pH range of the present enzyme is about 4.0-10.0. In a pH range of 6.5-8.5, the enzymatic activity is maintained at 100%, and in pH ranges exceeding 4.0 up to less than 6.5, and exceeding 8.5 up to 10.0, the enzymatic activity is maintained at 80-100%.

(3) Thermal stability

The present enzyme was maintained for 15 minutes at various temperatures in a buffer solution containing 2 mM calcium chloride at pH 7.8. In each case, the enzyme after this treatment was allowed to react with a substrate in accordance with the procedures described in the method for the measurement of enzymatic activity mentioned above. The results indicated that under the aforesaid conditions the present enzyme is stable at temperatures up to 60 °C. When the present enzyme was similarly kept in solutions not containing calcium chloride, it was stable at temperatures up to 50 °C.

(4) Effect of inhibitors

The present enzyme is completely inhibited by diisopropyl fluorophosphate (DFP). This fact indicates that the present enzyme is classified as a serine protease.

The present enzyme is also completely inhibited by Z-Phe Leu Glu CH₂Cl. This fact indicates that the present enzyme is a glutamic acid specific endopeptidase.

The present enzyme is partially inhibited by EDTA, with a maximum inhibition ratio of approximately 72%. This inhibitory effect of EDTA is completely nullified by the addition of metal ions at low concentrations (10⁻⁴ to 10⁻³ M of calcium or magnesium ions, etc.).

The aforesaid facts indicate that the present enzyme is a typical serine protease, the stability of which is related to the presence of metal ions.

(5) Molecular weight

The molecular weight of the present enzyme was determined by SDS-PAGE using 15% gel (1.0 mm) and Rainbow™ Protein Molecular Weight Marker (Amersham), and was calculated to be 26,000. The molecular weight was also calculated from the amino acid sequence determined on the basis of the gene sequencing analysis to be described below, and the value so obtained was 23,567 which is somewhat different from the aforesaid value obtained by SDS-PAGE. Nevertheless, the results of the various protein chemical analyses to be described below (amino acid composition, amino terminal sequences, amino acid composition in the vicinity of the carboxyl terminus) agreed well with the structure deduced from the DNA sequence. This indicates that the molecular weight obtained by SDS-PAGE was, in fact, slightly in excess of the true value.

(6) Isoelectric point

Investigation of the isoelectric point of the present enzyme using the Pharmacia FAST System (Pharmalite, pH 3.0-10.0) yielded values above pH 9.0, and a normal value could not be obtained.

(7) Amino acid composition

Using 4 M methanesulfonic acid (containing 0.2% of 3-(2-aminoethyl)indole), the present enzyme was hydrolyzed at 110°C for prescribed time intervals (24, 48, or 72 hours). The respective hydrolysates were then subjected to amino acid analysis using a Hitachi Model 835 amino acid analyzer. The results of this analysis, corrected for the decomposition of amino acids in the process of hydrolysis, are shown in Table 2. The amino acid composition calculated from the DNA sequence of the present enzyme (described below) are also shown for comparison in Table 2. The two sets of results clearly display good agreement.

Table 2 Amino acid composition

Amino acid	Measured value (%)	Calculated value (%)
Asp	8.38	8.10
Thr	11.68	12.61
Ser	13.49	14.41
Glu	5.48	4.95

Val	6.08	5.86
Met	0.93	0.90
Ile	6.04	5.86
Leu	2.34	2.25
Tyr	7.97	7.66
Phe	2.38	2.25
Lys	2.70	2.70
His	1.73	1.80
Arg	4.11	4.05
Trp	1.37	1.80
Total	100.01	99.97

(8) Partial amino acid sequences

(i) Amino acid sequence near N terminus

5 A Model 477A Protein Sequencer (Applied Biosystems) was used to analyze the amino acid sequence of the present enzyme in the vicinity of the amino terminus. The enzyme samples used were inhibited beforehand with DFP. The amino acid sequence from the amino terminus to the 23rd residue is shown in Table 3.

Table 3

Degradation step	Amino acid	Recovery (%)	Degradation step	Amino acid	Recovery (%)
1	Ser	24.1	13	Asn	53.2

11	Val	65.3	23	Val	22.7
12	Thr	36.4			

(ii) Amino acid sequence near C terminus

Carboxypeptidase A (CPase A) or carboxypeptidase Y (CPase Y) was allowed to act upon samples of the present enzyme inhibited beforehand with DFP, and the quantities of amino acids released by these reactions were measured with an amino acid analyzer of Hitachi Model 835. However, the amino acid sequence in the vicinity of the carboxyl terminus of the present enzyme could not be accurately determined using either of the aforesaid carboxypeptidases. Nevertheless, the presence of glutamine, serine, alanine and asparagine in the vicinity of the carboxyl terminus was verified.

V. Determination of DNA sequence encoding BLase

Certain terminology employed in the specification of the present invention is defined as follows.

"Oligonucleotide" refers to a short single-strand DNA molecule. Oligonucleotides can be chemically synthesized in accordance with known methods. Unless otherwise stated, the oligonucleotides used in the processes of the present invention are chemically synthesized, and are purified by gel chromatography using Sephadex G50 and high-performance liquid chromatography (HPLC) with a reverse phase silica gel column.

"PCR" is an acronym of "polymerase chain reaction", and refers to a method for enzymatic amplification of a definite DNA region (Saiki et al., Science, 239, 487-497, 1988). First, the DNA to be amplified is converted to single-strand form by thermal denaturation, and oligonucleotide primers (two types, i.e., sense and antisense strands, each having a complementary sequence to the 3'-terminal region of the said single-stranded DNA) are annealed to the regions at the respective 3'-termini of the single-stranded DNA (i.e., the template DNA). Next, the extension of the DNA strands from the respective primers is accomplished by a reaction using DNA polymerase. By repeating this sequence of reactions, the target DNA can be amplified by a factor of 100,000 to 1,000,000.

"Southern blotting" is a method for determining whether or not a specified gene is contained in a DNA fragment obtained by cleavage with a certain restriction enzyme. Southern blotting is performed by first digesting the DNA sample under investigation with a restriction enzyme which specifically recognizes a certain base sequence in duplex DNA and cleaves this DNA at specific sites. The digest so obtained is subjected to 1% agarose gel electrophoresis, then denatured into single-stranded DNA by alkali treatment, and transferred to a nylon filter. Separately, an oligonucleotide or DNA fragment constituting a portion of the gene in question is prepared and labelled to obtain a probe. Hybridization of the single-stranded DNA on the nylon filter with this probe is then used to detect the presence of the gene in question.

"Ligation" refers to the creation of phosphodiester bond between two duplex DNA fragments. In this technique, in order to prevent the self-ligation of the duplex DNA fragments, one of the fragments is subjected to prior dephosphorylation treatment by the conventional method (T. Maniatis et al., "Molecular Cloning", 133-134, 1982). Ligation can be accomplished with T4 DNA ligase, using a well known type of buffer solution and reaction conditions.

"Transformation" refers to the phenomenon wherein the genotype of a cell (i.e., a host cell) is transformed by the introduction of exogenous genes (DNA) into the said cell. A cell which has undergone such a transformation is known as a "transformant", and is characterized by the capability for replication of the exogenous DNA either as an extranuclear component or in a form integrated into the chromosomes of the said cell.

Next, the method employed for the determination of the DNA sequence of BLase of the present invention will be described in the order of the processes involved. This DNA sequence was determined by the analysis of the genome DNA of the *Bacillus licheniformis* ATCC No. 14580 using a combination of PCR analysis, Southern blotting, direct sequencing techniques, etc.

(1) PCR analysis of genome DNA sequence

A DNA sequence encoding BLase can be obtained, for example, from genome DNA. In order to obtain the DNA, first, the genome DNA of *Bacillus licheniformis* ATCC No. 14580 is isolated from cultured cells of the said strain by the conventional technique (M. Stahl et al., J. Bacteriology, 154, 406-412, 1983). This genome DNA is used as the template DNA for PCR analysis. The oligonucleotide primers used for PCR are synthesized by conventional methods on the basis of the amino acid sequence in the vicinity of the amino terminus of the purified enzyme, determined in Section IV Item (8) above, and/or the amino acid sequences of the peptides obtained by partial hydrolysis of the said enzyme. For example, the oligonucleotide encoding the amino acid sequence Thr Asn Thr Thr Ala Tyr Pro Tyr which corresponds to the 12th through 19th positions reckoned from the amino terminus of BLase (see Table 3) is used as sense primer BL8 (shown by SEQ ID NO: 2). This oligonucleotide is a tricosamer which encodes the amino acid sequence

upto the second base of the triplet codon for the tyrosine residue of c-terminus.

5
 BL8: 5' - AC AACAC AC GCTTACCC TA
 C C C G

10 Separately, another oligonucleotide primer is synthesized on the basis of a peptide which is obtained by the decomposition of the purified enzyme with lysylendopeptidase followed by sequencing and the sequence of which is most reliable. As described in Example 2 below, the sequence Gly Tyr Pro Gly Asp Lys (SEQ ID NO: 8) is obtained, hence, the octadecamer complementary to an oligonucleotide encoding this amino acid sequence is used as antisense primer BL83 (shown by SEQ ID NO: 3).

15
 BL83: 5' - TT TC CC GGATA CC
 C G G A G

20 Then, PCR is performed using the aforesaid genome DNA, the sense primer BL8, and the antisense primer BL83, thereby extending and amplifying the target DNA strands in the genome DNA. The PCR products so obtained are subjected to agarose gel electrophoresis, thereby obtaining a DNA fragment of approximately 370 bp. This DNA fragment is incorporated into a suitable vector, and after subcloning, the base sequence of the fragment is determined by the Sanger technique. The aforesaid amino acid sequence Gly Tyr Pro Gly Asp Lys which constituted the basis for the preparation of the antisense primer BL83 was identified as that located in positions 131-136 in the amino acid sequence of BLase.

(2) Southern blotting analysis of genome DNA

30 The genome DNA derived from the *Bacillus licheniformis* ATCC No. 14580, prepared in Item (1) above, is digested with the restriction enzyme *Sall*, and after separation by agarose gel electrophoresis, the DNA fragments so obtained are blotted onto a nylon membrane filter, and analyzed by the Southern technique. The probe used for hybridization is the BL8-BL83 PCR product obtained in Item (1) above, labelled with ³²P-dCTP by the conventional method. The DNA fragment which displays positive hybridization to this BL8-BL83 product is recognized as a band corresponding to a length of approximately 3.1 kb.

(3) Sequencing of genome DNA by PCR

40 The genome DNA of the *Bacillus licheniformis* ATCC No. 14580, obtained in Item (1) above, is digested with *Sall*, then this digest is incorporated into a suitable vector, for example, pUC119 vector, and a PCR is conducted using a portion of the known DNA sequence as a primer. For example, a portion of the DNA sequence of pUC119 located upstream to the aforesaid genome DNA is used as sense primer RV (shown by SEQ ID NO: 4), and a DNA sequence complementary to a sequence in the vicinity of the 3' terminus of the 375 bp DNA fragment analyzed in Item (2) above is used as antisense primer B125 (shown by SEQ ID NO: 5).

RV: 5' - CAGGAAACAGCTATGAC

B125: 5' - TGCCCCAACAAGTGATGA

50 A DNA fragment of approximately 1050 bp is obtained by the PCR. The base sequence of this fragment can be determined by the direct DNA sequencing method (Gibbs et al., *Pro. Natl. Acad. Sci. U.S.A.*, **86**, 1919-1923, 1989). In this manner, the DNA sequence encoding BLase can be ascertained from the amino terminus up to the middle portion of the sequence.

Next, the portion of the sequence on the 3' side of the genome DNA can be determined by the following procedure. First, in the same manner as indicated above, the genome DNA of *Bacillus licheniformis* ATCC No. 14580 is digested with *Sall*, and a fragment of approximately 3.1 kb is isolated. This is inserted into M13mp11, and a PCR is conducted. The primers used for this PCR are partial fragments of the 375 bp DNA fragment analyzed in Item (2) above; one is sense primer B40 (shown by SEQ ID NO: 6) which is located upstream to the aforesaid antisense primer B125, and the other is antisense primer M4

(shown by SEQ ID NO: 7) which has a DNA sequence complementary to a portion of the DNA sequence of M13mp11, and is located downstream to the genome DNA.

B40: 5' - AAAACCGTCGCAACAGCC

M4: 5' - GTTTTCCCAGTCACGAC

5 The aforesaid PCR yields a DNA fragment of approximately 2.2 kb. The base sequence of this DNA fragment can be determined by the direct DNA sequencing method. In this manner, the base sequence from the 3' terminus to the middle portion of the genome DNA is determined.

The complete DNA sequence of BLase determined in this manner as well as the amino acid sequence determined from this DNA sequence are shown in SEQ ID NO: 1 and Figure 1. From SEQ ID NO: 1 and
 10 Figure 1, it is recognized that the gene encoding the mature protein derived from *Bacillus licheniformis* contains a DNA sequence encoding a signal peptide composed of the 94 amino acid residues from N-formylmethionine residue in the -94 position to the lysine residue in the -1 position, and a DNA sequence encoding the mature protein composed of the 222 amino acid residues from the serine residue in the +1 position to the glutamine residue at the +222 position. Ordinarily, ATG codes for methionine, but in this
 15 case TTG (fMet) appears to be the translation start codon. In the 332 bp segment of the 5' untranslated region starting from the *Sall* cleavage site, there are a promoter region containing a -35 sequence, a Pribnow box, and a Shine-Dalgarno sequence which is present 9 bases upstream from the aforesaid inferred translation start codon TTG. In the 3' untranslated region, an inverted complementary repeat composed of 13 base pairs is located 8 bases downstream from the stop codon TAA.

20

VI. Construction of expression vectors

As shown in Figure 2, pHY300BLtt, an example of the expression vectors of the present invention, is obtained from the shuttle vector pHY300PLKtt, which contains an alkaline protease terminator derived from
 25 *Bacillus subtilis* ATCC No. 6051, by inserting a DNA fragment encoding BLase of the present invention shown in SEQ ID NO: 1 (i.e., a DNA fragment containing a promoter, a DNA sequence encoding a signal peptide, a DNA sequence encoding the mature peptide of BLase, and a terminator) into the said vector pHY300PLKtt. As shown in Figure 3, the aforesaid vector pHY300PLKtt is obtained from a vector pHY300PLK which is a shuttle vector of *E. coli* and *B. subtilis*, by inserting an alkaline protease terminator
 30 derived from *Bacillus subtilis* ATCC No. 6051 into the vector pHY300PLK.

The aforesaid procedure will now be further explained in the order of the processes involved. First, as shown in Figure 3, genome DNA is isolated from the *Bacillus subtilis* ATCC No. 6051 by the method of M. Stahl et al. (supra.), and this is employed as template DNA. Next, a fragment composed of a DNA sequence corresponding to the vicinity of the 5' terminus of the terminator portion of the alkaline protease gene
 35 derived from the *Bacillus subtilis* I-168, with an added *Xba*I cleavage site, and a fragment complementary to a DNA sequence corresponding to the vicinity of the 3' terminus of the terminator portion, with an added *Hind*III cleavage site, are synthesized chemically, and a PCR is conducted using these fragments as primers. The DNA fragment so obtained is then cleaved with *Xba*I and *Hind*III, thereby obtaining a fragment
 (1) shown in Figure 3. Next, pHY300PLK is cleaved with *Xba*I and *Hind*III, thereby obtaining the larger
 40 fragment (2) shown in Figure 3. The shuttle vector pHY300PLKtt, containing the alkaline protease terminator derived from *Bacillus subtilis* ATCC No. 6051, is then constructed by the ligation of these fragments (1) and (2).

Next, genome DNA is isolated from cultured cells derived from *Bacillus licheniformis* ATCC No. 14580 and used as template DNA. Then, a fragment composed of a DNA sequence corresponding to the vicinity
 45 of the 5' terminus of this template DNA with an added *Eco*RI cleavage site and a fragment complementary to the DNA sequence corresponding to the 3' terminus of the template DNA with an added *Xba*I cleavage site are synthesized and used as the sense and antisense primers, respectively. A PCR is conducted using the aforesaid template DNA, sense primer, and antisense primer. Then, the fragment so obtained is cleaved
 with *Eco*RI and *Xba*I, thereby obtaining a DNA fragment (3) encoding BLase (see Figure 2). This fragment
 50 (3) contains a promoter, a DNA sequence encoding a signal peptide, a DNA sequence encoding mature BLase, and a terminator. Next, the aforesaid vector pHY300PLKtt is cleaved with *Eco*RI and *Xba*I, thereby obtaining the larger fragment (4). The expression vector pHY300BLtt of the present invention is then obtained by ligating the aforesaid fragments (3) and (4) (see Figure 2).

This expression vector pHY300BLtt contains, under the control of the BLase promoter, a DNA sequence
 55 encoding the signal peptide from the N-formylmethionine residue in the -94 position to the lysine residue in the -1 position; a DNA sequence encoding a mature peptide extending from the serine residue in the +1 position to the glutamine residue in the +222 position of BLase; and a 3' untranslated region comprising a terminator. Still further downstream, the terminator of the alkaline protease derived from *Bacillus subtilis*

ATCC No. 6051 is present.

VII. Preparation of transformants and production of BLase

5 The expression vector obtained in Section VI above is introduced into suitable host cells by a conventional method. For example, the aforesaid vector pHY300BLtt can be introduced into *Bacillus subtilis* ISW1214 (Takara Shuzo) by the method of J. Spiezen et al. (Proc. Natl. Acad. Sci. U.S.A. 44, 1072, 1958). The transformant (*Bacillus subtilis* pHY300BLtt/ISW1214) is cultivated in any medium suitable for the host, thereby producing BLase of the present invention. Finally, BLase is isolated from the culture broth wherein
10 the transformant has been grown and purified by the process described in Section II above.

EXAMPLES

The present invention will now be further explained with reference to the specific examples.

Example 1

Bacillus licheniformis ATCC No. 14580 was cultivated at 28 °C for 36 hours in a medium of pH 7.0 containing 2.0% of glucose, 2.0% of soybean meal, 0.25% of corn steep liquor, 0.5% of ammonium sulfate, 0.05% of dipotassium hydrogen phosphate, 0.05% of magnesium sulfate heptahydrate, 0.01% of ferrous sulfate heptahydrate, and 0.3% of calcium carbonate. Ninety five liters of the culture broth were filter pressed, and concentrated to approximately 14 liters by means of an ultrafiltration module (Nitto Ultrafiltration Module NTU 2020T P18B (HF); cutoff MW 20,000) and a centrifuge (4200 rpm, 30 minutes). This concentrated cell-free broth was diluted to approximately 28 liters (1.90 ms/cm) with 2 mM calcium chloride.
20 Then the pH of the diluted cell-free broth was adjusted to 6.0 by addition of hydrochloric acid. To this was added approximately 4 liters of Amberlite CG-50 which had been equilibrated with a 10 mM acetate buffer (pH 6.0) containing 2 mM calcium chloride, and the mixture was agitated for 4 hours at room temperature. After verifying that the supernatant had no BLase activity, the supernatant was discarded. Then the Amberlite CG-50 was packed into a 14 x 32 cm glass column. After washing with approximately 10 liters of
30 10 mM acetate buffer (pH 6.0) containing 2 mM calcium chloride, elution was performed with 0.5 M sodium acetate buffer (pH 8.5) also containing 2 mM calcium chloride.

The fractions having BLase activity eluted from the Amberlite CG-50 were combined (the total volume of the fractions was 2.7 liters) and dialyzed against water for 48 hours. The dialyzate was diluted to 8 liters (2.23 ms/cm) with 2 mM calcium chloride, and after adjustment to pH 6.0, the fluid was adsorbed onto approximately 800 ml of S-Sepharose, packed in a 5 x 40 cm column, which had been equilibrated beforehand with a 5 mM acetate buffer solution (pH 6.0) containing 2 mM calcium chloride. After washing with approximately 5 liters of buffer solution with the same composition as that used for the above-mentioned equilibration, the column was subjected to elution with 7 liters of this buffer solution under a linear gradient of 0-0.2 M sodium chloride. The fractions having BLase activity were combined (the total volume of the fractions was 900 ml), and dialyzed overnight against a 2 mM aqueous solution of calcium chloride, thereby obtaining approximately 950 ml of dialyzate (0.86 ms/cm). The pH of this dialyzate was adjusted to 7.5, then promptly subjected to affinity chromatography. The carrier used in this affinity chromatography process was approximately 340 ml of CH Sepharose 4B (Phe Leu-D-GluOMe) packed into a 3 x 48 cm column, and equilibrated with 5 mM Tris-HCl (pH 7.5) containing 2 mM calcium chloride. After
40 adsorbing the aforesaid dialyzate in this column, the column was washed with approximately 5 liters of buffer solution with the same composition as that used for equilibration of the column, and then subjected to elution with 3.5 liters of the buffer solution of the same composition under a linear gradient of 0-0.7 M sodium chloride.

The BLase activity of each fraction so obtained was measured by the method for the measurement of enzymatic activity shown in Section III of Description of the preferred Embodiments. The results are shown in Figure 4. The 280 nm absorbance of each fraction was measured as an index of protein concentration, and the results so obtained are also shown in Figure 4. This figure shows that the BLase was eluted at a concentration of approximately 0.5 M of sodium chloride. The BLase so obtained displayed a single band in SDS-PAGE. In this manner, an 833.1 mg specimen of the said enzyme (quantitated with a Bio Rad protein assay kit), with specific activity of $1.9 \times 10^3 - 2 \times 10^3$ U/mg, was obtained from 95 liters of the culture broth.
55 The yield of the enzymatic activity was 27.5%.

Example 2

Determination of base sequence of DNA encoding BLase

5 (1) PCR analysis of internal base sequence of genome DNA

One hundred micrograms of the purified BLase obtained in Example 1 which had been treated with DFP was added in 150 μ l of 0.05 M Tris-HCl (pH 9.0) containing 1 M urea, and digested with 1 μ g of lysyl endopeptidase (Wako Pure Chemical Industries, Ltd.) at 37°C for 5 hours. The resulting enzyme digest was then isolated and purified by high-performance liquid chromatography using a column packed with TSKgel ODS-120T (4.6 x 250 mm, Tosoh Co. Ltd.) The amino acid sequences of the digested fragments so obtained were investigated with a Model 477A Protein Sequencer (Applied Biosystems), thereby determining the amino acid sequences of five types of fragments. Three of these sequences are indicated below as well as in SEQ ID NOS: 8, 9, and 10.

15 Gly-Tyr-Pro-Gly-Asp-Lys (I)
Ala-Ile-Val-His-Ile (II)
Ser-Thr-Arg-Tyr-Phe-Ile-Pro-Ser (III)

Next, genome DNA was isolated from *Bacillus licheniformis* ATCC No. 14580 by the method of M. Stahl et al. (supra.), and the DNA was used as a template for PCR analysis. The oligonucleotide primers used for the PCR were prepared on the basis of known portions of the amino acid sequence of the BLase produced by *Bacillus licheniformis* ATCC No. 14580. First, an oligonucleotide encoding the amino acid sequence beginning with the 12th position and terminating with the 19th position from the amino terminus of the BLase molecule (see Table 3), that is, Thr Asn Thr Thr Ala Tyr Pro Tyr (except that the said oligonucleotide only extends through the second base of the triplet coding for the tyrosine residue at the carboxyl terminal of the oligopeptide, i.e., the said oligonucleotide is a tricosamer) was synthesized chemically. This was used as sense primer BL8 (shown by SEQ ID NO: 2).

30
BL8: 5' - T T T A
AC AACAC AC GCTTACCC TA
C C C G

Next, an octadecamer complimentary to the DNA sequence encoding an amino acid fragment which is a product obtained in the aforesaid lysyl endopeptidase digestion and which has an amino acid sequence with the greatest degree of reliability [i.e., Gly Tyr Pro Gly Asp Lys (shown by SEQ ID NO: 8)] was synthesized chemically. This was used as antisense primer BL83 (shown by SEQ ID NO: 3).

40
BL83: 5' - T A T C T
TT TC CC GGATA CC
C G G A G

45 Using the aforesaid template DNA and oligonucleotide primers, the DNA was amplified by the PCR method (Saiki et al., Science 239, 487-491, 1989). A portion of the amplified products were analyzed by 1% agarose gel electrophoresis, thereby confirming the presence of an approximately 370 bp DNA fragment. This fragment was isolated and, after blunting the ends with Klenow fragment, the fragment was cloned in M13mp11 which had been digested with *Sma*I, and the DNA sequence of the fragment was determined by the Sanger method (Sanger et al., Proc. Natl. Acad. Sci. U.S.A., 74, 5463-5467, 1977). In this manner, the base sequence of a 375 bp fragment was determined, and the amino acid sequence corresponding to BL83 was found to be located at positions 131 through 136. Furthermore, the aforesaid amino acid sequences (II) and (III) were found to be located at positions 21 through 25 and 79 through 86, respectively.

55 (2) Southern blotting analysis of genome DNA

The genome DNA derived from *Bacillus licheniformis* ATCC No. 14580 obtained by the procedure described in Item (1) above was digested with the restriction enzyme *Sal*I, and after separation of the

products by 1% agarose gel electrophoresis, the DNA fragments were blotted onto a nylon membrane filter and analyzed by the Southern technique. The probe used for the hybridization was the BL8-BL83 PCR product obtained in Item (1) above, and labelled with ^{32}P -dCTP by the conventional method. The DNA fragment which displayed positive hybridization to this BL8-BL83 product was recognized as a band corresponding to a length of approximately 3.1 kb.

(3) Determination of genome DNA sequence by PCR

The genome DNA of *Bacillus licheniformis* ATCC No. 14580, obtained in Item (1) above, was digested with *Sall*, then the ends of the fragments were blunted with T4 DNA polymerase. This blunt-end fragment was ligated with a dephosphorylated *Sma*-digested pUC119 vector. This ligation reaction was performed with a commercial kit (Takara Shuzo).

Next, the sense primer RV (shown by SEQ ID NO: 4) and the antisense primer B125 (shown by SEQ ID NO: 5), with the base sequences also indicated below, were synthesized chemically and added to an aliquot of the reaction mixture for the aforesaid ligation reaction, allowing a PCR reaction to be carried out.

The sense primer RV is a portion of the DNA sequence of pUC119 and is located upstream to the aforesaid genome DNA, while the antisense primer B125 is a DNA sequence complementary to a sequence in the vicinity of the 3' terminus of the 375 bp DNA fragment analyzed in Item (2) above.

RV: 5' - CAGGAAACAGCTATGAC

B125: 5' - TGTCCCAACAGTGATGA

A DNA fragment of approximately 1050 bp was obtained by the aforesaid PCR. The base sequence of this fragment was determined by the direct DNA sequencing method (Gibbs et al., *Proc. Natl. Acad. Sci. U.S.A.*, 86, 1919-1923, 1989). In this manner, the DNA sequence encoding the present enzyme was ascertained from the 5' terminus up to the middle portion of the sequence.

The genome DNA of the *Bacillus licheniformis* ATCC No. 14580, obtained in Item (1) above, was digested with *Sall* and subjected to 1% agarose gel electrophoresis, thereby isolating an approximately 3.1 kb fragment. This fragment was blunt ended with Klenow fragment, and was ligated with dephosphorylated *Sma*-digested fragments of M13mp11. Using this as a template, a PCR was conducted. The primers used for this PCR were sense primer B40 (shown by SEQ ID NO: 6) which is a portion of the 375 bp DNA fragment analyzed in Item (2) above (upstream to the aforesaid primer B125), and antisense primer M4 (shown by SEQ ID NO: 7) which is a DNA sequence complementary to a portion of the DNA sequence of M13mp11 located downstream to the genome DNA.

M4: 5' - GTTTTCCCAGTCACGAC

B40: 5' - AAAACCGTCGCAACAGCC

The aforesaid PCR yielded an approximately 2.2 kb DNA fragment. The base sequence of this DNA fragment was determined by the direct DNA sequencing method. In this manner, the base sequence from the 3' end to the middle portion of the genome DNA was determined.

The complete DNA sequence of BLase determined in this manner as well as the amino acid sequence deduced from the DNA sequence are shown by SEQ ID NO: 1 and Figures 1-1 to 1-3.

The DNA sequence of BLase, as well as DNA sequences which hybridize to the said DNA sequence are also useful for producing a protease with BLase activity which is also within the scope of the present invention. The DNA sequence which hybridizes to the DNA sequence of BLase can be obtained, for example, by the following process.

Various DNA fragments, for example, DNA fragments derived from various organisms are screened by the use of whole or a part of the DNA sequence of BLase, e.g. a 1124 bp DNA fragment which is from A in the 248 position to T in the 1371 position of SEQ ID NO:1, as a probe. For example, the Southern hybridization technique (Southern, E. M., *J. Mol. Biol.* 98, 503-517, 1975) is employed by the use of the ^{32}P -labelled probe, and a hybridization buffer having the following composition.

0.5 M	NaH_2PO_4 (pH 7.2)
1 mM	EDTA
1%	BSA
7%	SDS

After the hybridization is carried out at 65 °C overnight, a filter, to which the probe has been hybridized, is washed 4 times at room temperature with 2 x SSC, 0.1% SDS, four times each wash being carried out for 10 minutes, at room temperature, thus obtaining a DNA fragment which has about 65% homology with the DNA sequence of BLase. When the filter is washed once for 20 minutes at 50 °C, a DNA fragment which has about 80% homology with the DNA sequence of BLase can be obtained.

(4) Construction of expression vector

(4)-1 Construction of shuttle vector pHY300PLKtt

A genome DNA was isolated from *Bacillus subtilis* ATCC No. 6051 by the method of M. Stahl et al. (supra.), and this was employed as a template DNA. Next, as primers, a fragment composed of a DNA sequence corresponding to the vicinity of the 5' terminus of the terminator portion of an alkaline protease gene derived from *Bacillus subtilis* I-168 (Journal of Bacteriology 158, 411-418, 1984), with an added XbaI cleavage site (sense primer A, shown by SEQ ID NO: 11), and a fragment complementary to a DNA sequence corresponding to the vicinity of the 3' terminus of the terminator portion, with an added HindIII cleavage site (antisense primer B, shown by SEQ ID NO: 12), were synthesized chemically.

Sense primer A:

5' - GAGTCTAGAGCAGCTGCACAATAATAG -3'

Antisense primer B:

5' - GAGAAGCTTGACAGAGAACAGAGAAG -3'

Then, a PCR was conducted using the aforesaid template DNA and these two primers. The DNA fragment so obtained was then cleaved with XbaI and HindIII, thereby obtaining fragment (1) shown in Figure 3. Next, the shuttle vector pHY300PLK (Takara Shuzo) was cleaved with XbaI and HindIII, thereby obtaining the larger fragment (2) (see Figure 3). A shuttle vector pHY300PLKtt, containing the alkaline protease terminator derived from *Bacillus subtilis* ATCC No. 6051, was then constructed by ligation of these fragments (1) and (2).

(4)-2 Construction of expression vector pHY300BLtt

A genome DNA was isolated from cultured cells of *Bacillus licheniformis* ATCC No. 14580 by the method of M. Stahl et al. (supra.) and used as a template DNA. Then, a single-stranded DNA fragment corresponding to the vicinity of the 5' terminus of this template DNA with an added EcoRI cleavage site and a single-stranded DNA fragment complementary to a DNA sequence corresponding to the 3' terminus of the template DNA with an added XbaI cleavage site were synthesized and used as sense primer C (shown by SEQ ID NO: 13) and antisense primer D (shown by SEQ ID NO: 14), respectively.

Sense primer C:

5'- CAAGAATTTCGGCTTCCCGTGCGCCTCC - 3'

Antisense primer D:

5'- TTGTCTAGAATTTGCCGATCAGCGGTC - 3'

A PCR was conducted using the aforesaid template DNA, sense primer C, and antisense primer D. Then, the fragment so obtained was cleaved with EcoRI and XbaI, thereby obtaining a DNA fragment (3) encoding BLase (see Figure 2). Next, the aforesaid vector pHY300PLKtt was cleaved with EcoRI and XbaI, thereby obtaining the larger fragment (4). The aforesaid fragments (3) and (4) were then ligated with T4 DNA ligase. The ligation mixture was used to transform *E. coli* K-12 C600. The transformants were cultivated on an agar plate medium containing ampicillin, and the ampicillin-resistant colonies were selected. Then, plasmid DNA was isolated from the cells of the selected colonies, and the insertion of the aforesaid DNA fragment (3) in the correct direction was verified from restriction enzyme cleavage patterns.

(5) Preparation of transformants and production of BLase

The expression vector pHY300BLtt obtained in Item (4) above was introduced into *Bacillus subtilis* ISW1214 (Takara Shuzo) by the method of J. Spizien et al. (Proc. Natl. Acad. Sci. U.S.A. 44, 1072 (1958)). The bacteria were then cultivated on a plated agar medium containing tetracycline, and the tetracycline-resistant colonies were selected, thus obtaining the desired transformant (*Bacillus subtilis* pHY300BLtt/ISW1214).

The transformant was transplanted to 5 ml of LB medium (10 g trypton, 5 g yeast extract, and 5 g sodium chloride with water added to yield a total volume of 1 liter; pH 7.2) and shake-cultured at 37 °C for

18 hours. Then, 1 ml of this culture broth was added to 10 ml of Sc⁺ medium which had been sterilized in an autoclave at 120 °C for 20 minutes, and shake-cultured was carried out at 28 °C.

Composition of Sc⁺ medium

Soluble starch	10g
Glycerol	5g
Bacto soytone	5g
CSL	2.5g
Yeast extract	1g
Calcium carbonate	3g

Water is added so that the total volume should be 1 L (pH 7.0)

The aforesaid culture broth was centrifuged at 2500 x g for 5 minutes, and the supernatant was obtained. The BLase activity of this supernatant was measured by the method for the measurement of enzymatic activity described in the Description of the Preferred Embodiments. The results of these measurements are shown in Table 4. The quantity of protein per liter of the culture broth was calculated on the basis of an assumed BLase specific activity of 2500 U/mg.

Table 4

Cultivation period (days)	BLase activity (units/ml)	Protein content (mg/L)
1	15	6.0
2	56	22.4
3	72	28.8
4	79	31.6
5	69	27.6

As described above, the present invention provides a new protease which specifically cleaves the peptide bonds at the carboxyl termini of glutamic acid residues in the amino acid sequences of polypeptides, a method for the preparation of the protease from bacteria of genus *Bacillus*, a DNA sequence encoding the protease, an expression vector containing the DNA sequence, a transformant obtained by introduction of the expression vector into a host, and a method for the production of the protease using the transformant. This type of protease can be utilized for a variety of purposes, such as protein analysis and cleavage of the peptide chains of fusion proteins at desired sites, etc.

50 Claims

1. A protease, derived from Bacillus licheniformis, which cleaves the peptide bonds at the carboxyl termini of glutamic acid residues in polypeptides, and which contains an amino acid sequence from serine in the +1 position to glutamine in the +222 position of SEQ ID NO: 1.

55

2. A protease of claim 1, derived from Bacillus licheniformis ATCC No. 14580.

3. A protease of claim 1, which has the following properties:

- (1) Optimal pH: approximately 8.0, and
(2) Stable pH range: pH 6.5-8.5 at 25 ° C.
4. A protease which contains an amino acid sequence from serine in the +1 position to glutamine in the +222 position of SEQ ID NO: 1, and cleaves the peptide bonds at the carboxyl termini of glutamic acid residues in polypeptides.
5. A DNA sequence encoding a protease of claim 1 or claim 4.
6. A DNA sequence of claim 5, which contains a base sequence from the thymine residue in the 605 position to the adenosine residue in the 1270 position of SEQ ID NO: 1.
7. A DNA sequence of claim 5, which encodes a protease containing an amino acid sequence from N-formylmethionine at the -94 position to the glutamine at the +222 position of SEQ ID NO: 1.
8. A DNA sequence of claim 7, which contains a base sequence, from the thymine residue in the 323 position to the adenosine residue in the 1270 position, of SEQ ID NO: 1.
9. An expression vector containing a DNA sequence of claim 5.
10. An expression vector of claim 9, which is expressible in bacteria of the genus Bacillus.
11. A transformant obtainable by introducing the expression vector of claim 9 into a host.
12. A transformant of claim 10, wherein said host is a strain belonging to the genus Bacillus.
13. A method for producing a protease of claim 1 or 4, comprising the steps of cultivating a strain of Bacillus licheniformis capable of producing a protease of claim 1 or 4 in a culture medium and recovering the produced protease from the culture medium.
14. A method for producing a protease comprising the steps of cultivating a transformant of claim 11 in a culture medium and recovering the produced protease from the culture medium.

Patentansprüche

1. Protease, abgeleitet von Bacillus licheniformis, welche die Peptidbindungen in Polypeptiden an den Carboxy-Termini von Glutaminsäureresten spaltet, und welche eine Aminosäuresequenz von Serin an der Position +1 bis Glutamin an der Position +222 der SEQ ID NO:1 enthält.
2. Protease nach Anspruch 1, abgeleitet von Bacillus licheniformis ATCC Nr. 14580.
3. Protease nach Anspruch 1, welche die folgenden Eigenschaften aufweist:
(1) Optimaler pH-Wert: ungefähr 8,0, und
(2) Stabiler pH-Bereich: pH-Wert 6,5-8,5 bei 25 ° C.
4. Protease, die eine Aminosäuresequenz von Serin an der Position +1 bis Glutamin an der Position +222 der SEQ ID NO: 1 enthält, und die die Peptidbindungen in Polypeptiden an den Carboxy-Termini von Glutaminsäureresten spaltet.
5. DNA-Sequenz, die für eine Protease gemäß Anspruch 1 oder Anspruch 4 kodiert.
6. DNA-Sequenz nach Anspruch 5, die eine Basensequenz vom Thyminrest an der Position 605 bis zum Adenosinrest an der Position 1270 der SEQ ID NO: 1 enthält.
7. DNA-Sequenz nach Anspruch 5, die für eine Protease kodiert, welche eine Aminosäuresequenz von N-Formylmethionin an der Position -94 bis zum Glutamin an der Position +222 der SEQ ID NO: 1 enthält.

8. DNA-Sequenz nach Anspruch 7, die eine Basensequenz vom Thyminrest an der Position 323 bis zum Adenosinrest an der Position 1270 der SEQ ID NO: 1 enthält.
9. Expressionsvektor, der eine DNA-Sequenz gemäß Anspruch 5 enthält.
10. Expressionsvektor nach Anspruch 9, welcher in Bakterien der Gattung Bacillus exprimierbar ist.
11. Transformante, erhältlich durch Einführung des Expressionsvektors gemäß Anspruch 9 in einen Wirt.
12. Transformante nach Anspruch 10, wobei der Wirt ein Stamm ist, der zur Gattung Bacillus gehört.
13. Verfahren zur Herstellung einer Protease gemäß Anspruch 1 oder 4, umfassend die Schritte des Kultivierens eines Stammes von Bacillus licheniformis, welcher in der Lage ist, eine Protease gemäß Anspruch 1 oder 4 zu produzieren, in einem Kulturmedium, und des Gewinnens der produzierten Protease aus dem Kulturmedium.
14. Verfahren zur Herstellung einer Protease, umfassend die Schritte des Kultivierens einer Transformante gemäß Anspruch 11 in einem Kulturmedium, und des Gewinnens der produzierten Protease aus dem Kulturmedium.

Revendications

1. Une protéase, obtenue à partir de Bacillus licheniformis, qui clive les liaisons peptidiques au niveau de l'extrémité carboxylique des résidus acide glutamique dans les polypeptides, et qui contient une séquence aminoacide à partir d'une sérine à la position +1 jusqu'à une glutamine à la position +222 de SEQ ID NO: 1.
2. Une protéase selon la revendication 1, obtenue à partir de Bacillus licheniformis ATCC No. 14580.
3. Une protéase selon la revendication 1, qui a les propriétés suivantes :
(1) pH optimal : environ 8,0, et
(2) zone de stabilité du pH : pH 6,5 - 8,5 à 25 °C.
4. Une protéase qui contient une séquence aminoacide à partir d'une sérine en position +1 jusqu'à une glutamine en position +222 de SEQ ID NO: 1, et qui clive les liaisons peptidiques au niveau de l'extrémité carboxylique des résidus acide glutamique dans les polypeptides.
5. Une séquence ADN codant pour une protéase selon la revendication 1 ou selon la revendication 4.
6. Une séquence ADN selon la revendication 5, qui contient une séquence en bases à partir du résidu thymine à la position 605 jusqu'au résidu adénosine à la position 1270 de SEQ ID NO: 1.
7. Une séquence ADN selon la revendication 5, qui code pour une protéase contenant une séquence aminoacide à partir d'une N-formylméthionine à la position -94 jusqu'à une glutamine à la position +222 de la SEQ ID NO: 1.
8. Une séquence ADN selon la revendication 7, qui contient une séquence en bases, à partir du résidu thymine à la position 323 jusqu'au résidu adénosine à la position 1270, de SEQ ID NO: 1.
9. Un vecteur d'expression contenant une séquence ADN selon la revendication 5.
10. Un vecteur d'expression selon la revendication 9, qui est exprimable dans des bactéries du genre Bacillus.
11. Un transformant que l'on peut obtenir en introduisant le vecteur d'expression de la revendication 9 dans un hôte.

EP 0 482 879 B1

12. Un transformant selon la revendication 10, pour lequel ledit hôte est une souche appartenant au genre Bacillus.
- 5 13. Un procédé de production d'une protéase selon la revendication 1 ou 4, comprenant les étapes de culture d'une souche de Bacillus licheniformis capable de produire une protéase selon la revendication 1 ou 4 dans un milieu de culture et de récupération de la protéase produite à partir du milieu de culture.
- 10 14. Un procédé de production d'une protéase comprenant les étapes de culture d'un transformant selon la revendication 11 dans un milieu de culture et de récupération de la protéase produite à partir du milieu de culture.
